Ferdowsi University of Mashhad

Reference for this lecture:
What is MPP?

Remember a P-V characteristic:

For any given set of operational conditions, cells usually have a single operating point where the values of the Current (I) and Voltage (V) of the cell result in a maximum power output.

The voltage at which PV module can produce maximum power is called ‘maximum power point’.

Maximum power varies with solar radiation and solar cell temperature.
A load with resistance $R = \frac{V_{\text{max}}}{I_{\text{max}}}$ which draws maximum power from the device, is sometimes called the characteristic resistance of the cell.

This is a dynamic quantity which changes depending on the level of illumination, as well as other factors such as temperature and the age of the cell.

Maximum power point trackers utilize different types of control circuit or logic to search for this point and thus to allow the converter circuit to extract the maximum power available from a cell.
Maximum Power Point Tracking

**MPPT** or Maximum Power Point Tracking is an algorithm used for extracting maximum available power from a PV module under certain conditions.

It is the purpose of the MPPT system to sample the output of the cells and apply the proper resistance (load) to obtain maximum power for any given environmental conditions.
How does a MPPT work?

Output resistance $R_o$ remains constant and by changing the duty cycle the input resistance $R_i$ seen by the source changes. So the resistance corresponding to the peak power point is obtained by changing the duty cycle.

\[
\frac{V_o}{V_i} = \frac{1}{1 - D}
\]

\[
\frac{I_o}{I_i} = 1 - D
\]

\[
R_i = \frac{V_i}{I_i} = \frac{V_o}{I_o} (1 - D)^2
\]

\[
R_i = R_o (1 - D)^2
\]
How does a MPPT work?

PV \xrightarrow{25V} 2.4A \rightarrow \sqrt{240}V \rightarrow \sqrt{15}A \rightarrow Load

PV \xrightarrow{10V} 2.5A \rightarrow Load \xrightarrow{R=4\ \Omega} 25W

\sqrt{240}V \rightarrow \sqrt{15}A \rightarrow R=10.4\ \Omega \rightarrow Load

\fbox{PV} \quad \fbox{Converter} \quad \fbox{Load}

\text{Convert}
How does a MPPT work?

MPPT is used for extracting the maximum power from the solar PV module and transferring that power to the load.

A dc/dc converter acts as an interface between the load and the module.

By changing the duty cycle, the load impedance as seen by the source is varied and matched at the point of the peak power with the source so as to transfer the maximum power.
Maximum Power Point Tracking Methods

MPPT Methods

- P&O (Perturbation and Observation)
  - Increment Conductance
  - Fractional Open-Circuit Voltage
  - Fractional Short-Circuit Current
  - Fuzzy Logic Control
  - Neural Network
  - RCC (Ripple Correlation Control)
  - Current Sweep
  - Load Current or Load Voltage Maximization
  - DC-Link Capacitor Voltage
  - \( \frac{dP}{dV} \) or \( \frac{dP}{dI} \) Feedback Control
P&O Involves a perturbation in the operating voltage of the PV array.

For a buck converter

Large D (near 1)

Small D (near 0)

P

P_{MPP}

V_{MPP} or I_{MPP}

V

\[ P(k) = V(k) \times I(k) \]

\[ \Delta P = P(k) - P(k-1) \]

\[ \Delta V = V(k) - V(k-1) \]

\[ D = \text{duty cycle} \]

\[ \Delta D = \text{perturbation.} \]
The process is repeated periodically until the MPP is reached. The system then oscillates around the MPP. The oscillation can be minimized by reducing the perturbation step size.

Solution:

- Variable step size algorithm
- Two-stage algorithm
P&O methods can fail under rapidly changing atmospheric conditions.

Starting from point A:

Voltage increases by $\Delta V$

- Fixed Irradiance
- Irradiance increased

Solution: Three-point weight comparison P&O method

Reversed perturbation

Perturbation is kept the same!!
Maximum Power Point Tracking Methods

MPPT Methods

P&O (Perturbation in the Operating voltage)

Increment Conductance

Fractional Open-Circuit Voltage

Fractional Short-Circuit Current

Fuzzy Logic Control

Neural Network

RCC (Ripple Correlation Control)

Current Sweep

Load Current or Load Voltage Maximization

DC-Link Capacitor Droop Voltage

dP/dV or dP/dI Feedback Control
Incremental Conductance

\[
\frac{dP}{dV} = \frac{d(IV)}{dV} = I + V \frac{dI}{dV} \approx I + V \frac{\Delta I}{\Delta V}
\]

The MPP can thus be tracked by comparing the instantaneous conductance \((I/V)\) to the incremental conductance \((\Delta I/\Delta V)\).
Incremental Conductance

$V_{\text{ref}}$ is the reference voltage at which the PV array is forced to operate.
Once the MPP is reached, the operation of the PV array is maintained at this point unless a change in $\Delta I$ is noted, indicating a change in atmospheric conditions and the MPP.

Fast tracking can be achieved with bigger increments but the system might not operate exactly at the MPP and oscillate about it instead; so we need a tradeoff.

The increment size determines how fast the MPP is tracked.
Maximum Power Point Tracking Methods

MPPT Methods

- P&O (Perturbation in the Operating voltage)
- Increment Conductance
- **Fractional Open-Circuit Voltage**
- Fractional Short-Circuit Current
- Fuzzy Logic Control
- Neural Network
- RCC (Ripple Correlation Control)
- Current Sweep
- Load Current or Load Voltage Maximization
- DC-Link Capacitor Droop Voltage
- \( \frac{dP}{dV} \) or \( \frac{dP}{dI} \) Feedback Control
Fractional Open-Circuit Voltage

The near linear relationship between $V_{MPP}$ and $V_{OC}$ of the PV array, under varying irradiance and temperature levels, has given rise to the fractional $V_{OC}$ method.

$$V_{MPP} \approx k_1 V_{oc} \quad 0.71 < k_1 < 0.78$$

- $k_1$ is dependent on the characteristics of the PV array being used.
- $V_{oc}$ is measured periodically by momentarily shutting down the power converter.
- Disadvantage: Temporary loss of power
Voltage generated by pn-junction diodes is approximately 75% of VOC

\[ V_{\text{junction}} \approx 0.75 V_{\text{oc}} \]

This eliminates the need for measuring \( V_{\text{OC}} \) and computing \( V_{\text{MPP}} \).

Once VMPP has been approximated, a closed-loop control on the array power converter can be used to asymptotically reach this desired voltage.

This method is only an approximation so, the PV array technically never operates at the MPP.

It is very easy and cheap to implement as it does not necessarily require DSP or microcontroller control.
Maximum Power Point Tracking Methods

P&O (Perturbation in the Operating voltage)
Increment Conductance
Fractional Open-Circuit Voltage
**Fractional Short-Circuit Current**
Fuzzy Logic Control
Neural Network
RCC (Ripple Correlation Control)
Current Sweep
Load Current or Load Voltage Maximization
DC-Link Capacitor Droop Voltage
dP/dV or dP/dI Feedback Control
Under varying atmospheric conditions, $I_{MPP}$ is approximately linearly related to the $I_{SC}$ of the PV array.

$$I_{MPP} \approx k_2 I_{SC} \quad 0.78 < k_2 < 0.92$$

Measuring $I_{SC}$ during operation is problematic. An additional switch usually has to be added to the power converter to periodically short the PV array so that ISC can be measured using a current sensor.

This increases the number of components and cost.

Most of the PV systems using fractional $I_{SC}$ in the literature use a DSP.
Maximum Power Point Tracking Methods

MPPT Methods

- P&O (Perturbation in the Operating voltage)
- Increment Conductance
- Fractional Open-Circuit Voltage
- Fractional Short-Circuit Current
- **Fuzzy Logic Control**
- Neural Network
- RCC (Ripple Correlation Control)
- Current Sweep
- Load Current or Load Voltage Maximization
- DC-Link Capacitor Droop Voltage
- $dP/dV$ or $dP/dI$ Feedback Control
Microcontrollers have made using fuzzy logic control popular for MPPT over the last decade.

Fuzzy logic control generally consists of three stages:

1. Fuzzification
2. Rule base table
3. Defuzzification
1. Fuzzification

Numerical input variables are converted into linguistic variables based on a membership function. The inputs are error E and change in error ΔE.

\[
E(n) = \frac{P(n) - P(n-1)}{V(n) - V(n-1)} \quad \Delta E(n) = E(n) - E(n-1)
\]

Five fuzzy levels are used: NB (negative big), NS (negative small), ZE (zero), PS (positive small), and PB (positive big).
2. Rule base table

Fuzzy logic controller output, which is typically a change in duty ratio $\Delta D$ of the power converter, can be looked up in a rule base table.

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
E & \Delta E & NB & NS & ZE & PS & PB \\
\hline
NB & ZE & ZE & NB & NB & NB & \\
NS & ZE & ZE & NS & NS & NS & \\
ZE & NS & ZE & ZE & ZE & PS & \\
PS & PS & PS & PS & ZE & ZE & \\
PB & PB & PB & PB & ZE & ZE & \\
\hline
\end{array}
\]

$E$ is PB, and $\Delta E$ is ZE, then we want to largely increase the duty ratio, that is $\Delta D$ should be PB to reach the MPP.
3. Defuzzification

Fuzzy logic controller output is converted from a linguistic variable to a numerical variable still using a membership function.

This provides an analog signal that will control the power converter to the MPP.
Fuzzy Logic Control

- The effectiveness depends a lot on the knowledge of the user in:
  1. choosing the right error computation
  2. coming up with the rule base table.

- MPPT fuzzy logic controllers have been shown to perform well under varying atmospheric conditions.
Maximum Power Point Tracking Methods

**MPPT Methods**

- P&O (Perturbation in the Operating voltage)
- Increment Conductance
- Fractional Open-Circuit Voltage
- Fractional Short-Circuit Current
- Fuzzy Logic Control
- Neural Network
- RCC (Ripple Correlation Control)
- Current Sweep
- Load Current or Load Voltage Maximization
- DC-Link Capacitor Droop Voltage
- $dP/dV$ or $dP/dI$ Feedback Control
Neural Network

Along with fuzzy logic controllers came another technique of implementing MPPT-neural networks, which are also well adapted for microcontrollers.

- Neural networks commonly have three layers:
  1. Input layer
  2. Hidden layer
  3. Output layer
The input variables can be:
1. PV array parameters like $V_{OC}$ and $I_{SC}$
2. Atmospheric data like irradiance and temperature or any combination of these.

The output is usually one or several reference signal(s) like a duty cycle signal.

To accurately identify the MPP, the $w_{ij}$’s have to be carefully determined through a training process.

Since most PV arrays have different characteristics, a neural network has to be specifically trained for the PV array with which it will be used.
Maximum Power Point Tracking Methods

MPPT Methods

- P&O (Perturbation in the Operating voltage)
- Increment Conductance
- Fractional Open-Circuit Voltage
- Fractional Short-Circuit Current
- Fuzzy Logic Control
- Neural Network

RCC (Ripple Correlation Control)

- Current Sweep
- Load Current or Load Voltage Maximization
- DC-Link Capacitor Droop Voltage
- $\frac{dP}{dV}$ or $\frac{dP}{dI}$ Feedback Control
When a PV array is connected to a power converter, the switching action of the power converter imposes voltage and current ripple on the PV array.

Ripple correlation control (RCC) makes use of ripple to perform MPPT.

RCC correlates time derivative of time varying PV array power with time derivative of PV array current or voltage to drive the power gradient to zero.
RCC (Ripple Correlation Control)

\[ \dot{p} > 0 \quad \text{or} \quad \dot{i} > 0 \]

\[ \begin{align*}
\dot{p} & > 0 \\
\dot{p} & < 0
\end{align*} \]

\[ \begin{align*}
(V & < V_{MPP} \quad \text{or} \quad I < I_{MPP}) \\
(V & > V_{MPP} \quad \text{or} \quad I > I_{MPP})
\end{align*} \]

Right of MPP

Left of MPP

\[ \begin{align*}
\dot{p} \dot{v} & \quad \text{or} \quad \dot{p} \dot{i} \\
+ & \quad \text{left of MPP} \\
- & \quad \text{right of MPP} \\
0 & \quad \text{MPP}
\end{align*} \]
RCC (Ripple Correlation Control)

\[ i \leq i_{mpp} \]

\[ i > i_{mpp} \]

\[ i = i_{mpp} \]
The duty ratio control input is:

\[ d(t) = -k_3 \int \dot{pv} \, dt \quad \text{or} \quad d(t) = k_3 \int \dot{pi} \, dt \]

When the power converter is a boost converter, increasing the duty ratio increases the inductor current, which is the same as the PV array current, but decreases the PV array voltage.

The derivatives are usually undesirable, but ac-coupled measurements of the PV array current and voltage can be used since they contain the necessary phase information.
RCC (Ripple Correlation Control)

- RCC accurately and quickly tracks the MPP, even under varying irradiance levels.
- Simple and inexpensive analog circuits can be used to implement RCC.
- Another advantage of RCC is that it does not require any prior information about the PV array characteristics, making its adaptation to different PV systems straightforward.
- The time taken to converge to the MPP is limited by the switching frequency of the power converter and the gain of the RCC circuit.
Maximum Power Point Tracking Methods

**MPPT Methods**

- P&O (Perturbation in the Operating voltage)
- Increment Conductance
- Fractional Open-Circuit Voltage
- Fractional Short-Circuit Current
- Fuzzy Logic Control
- Neural Network
- RCC (Ripple Correlation Control)

**Current Sweep**

- Load Current or Load Voltage Maximization
- DC-Link Capacitor Droop Voltage
- \( \frac{dP}{dV} \) or \( \frac{dP}{dI} \) Feedback Control
The current sweep method uses a sweep waveform for the PV array current such that the I–V characteristic of the PV array is obtained and updated at fixed time intervals.

The function chosen for the sweep waveform:

\[ f(t) = k_4 \frac{df(t)}{dt} \]

\[ f(t) = C \exp \left[ \frac{t}{k_4} \right] \]

\[ f(t) = I_{\text{max}} \exp \left[ -\frac{t}{\tau} \right]. \]

The current in can be easily obtained by using some current discharging through a capacitor.

\[ p(t) = v(t) i(t) = v(t) f(t). \]

At the MPP:

\[ \frac{dp(t)}{dt} = v(t) \frac{df(t)}{dt} + f(t) \frac{dv(t)}{dt} = 0. \]
In the current sweep method is implemented through analog computation.

Block schemes of the MPP computing unit:
The current sweep takes about 50 ms, implying some loss of available power.

It is pointed out that this MPPT technique is only feasible if the power consumption of the tracking unit is lower than the increase in power that it can bring to the entire PV system.
Maximum Power Point Tracking Methods

- P&O (Perturbation in the Operating voltage)
- Increment Conductance
- Fractional Open-Circuit Voltage
- Fractional Short-Circuit Current
- Fuzzy Logic Control
- Neural Network
- RCC (Ripple Correlation Control)
- Current Sweep

Load Current or Load Voltage Maximization
- DC-Link Capacitor Droop Voltage
- $\frac{dP}{dV}$ or $\frac{dP}{dI}$ Feedback Control
Load Current or Load Voltage Maximization

Traditional control via input parameters

Output parameters are sensed for protection anyways

Proposed control via output parameters

NO additional costs
Load Current or Load Voltage Maximization

Most Loads:

- Voltage-source type
- Current-source type
- Resistive type
- Combination

Voltage-source type: $i_{out} : \text{max} \quad \Rightarrow \quad \text{Output power} : \text{max}$

Current-source type: $v_{out} : \text{max} \quad \Rightarrow \quad \text{Output power} : \text{max}$

Other load types: $i_{out} \text{ or } v_{out}$ can be used.

Also true for nonlinear loads as long as they do not exhibit negative impedance.
Different load types:  
1. voltage source  
2. resistive  
3. resistive and voltage source  
4. current source,
Load Current or Load Voltage Maximization

Voltage-source type:

\[ i_{\text{out}} : \max \rightarrow \text{Output power} : \max \]

Change in \(d\)

\[ \begin{cases} I \uparrow & \text{The same change} \\ I \downarrow & \text{Reversed change} \end{cases} \]
Current-source type: \( v_{\text{out}} : \text{max} \rightarrow \text{Output power} : \text{max} \)

Change in \( d \):

\[
\begin{align*}
\text{The same change} & : V \\
\text{Reversed change} & : V
\end{align*}
\]
Advantages:

Sensing of a single output parameter.

No need for a multiplier

Simplified hardware (analog)
Simplified algorithm (digital)

Disadvantage:

Operation exactly at the MPP is almost never achieved because this MPPT method is based on the assumption that the power converter is lossless.
Maximum Power Point Tracking Methods

MPPT Methods

- P&O (Perturbation in the Operating voltage)
- Increment Conductance
- Fractional Open-Circuit Voltage
- Fractional Short-Circuit Current
- Fuzzy Logic Control
- Neural Network
- RCC (Ripple Correlation Control)
- Current Sweep
- Load Current or Load Voltage Maximization
- DC-Link Capacitor Droop Voltage
- \( \frac{dP}{dV} \) or \( \frac{dP}{dI} \) Feedback Control
DC-Link Capacitor Droop Voltage

Specifically designed to work with a PV system that is connected in parallel with an ac system line.

\[ d = 1 - \frac{V}{V_{link}} \]
**Operation Principle:**

- $V_{\text{link}}$ is kept constant (by current control on ac side)
- Change in duty ratio $d^*$ → Change in $P_{\text{array}}$
- Change in output power of converter
- Change in value of $I_{\text{peak}}^*$ (current command of inverter)

**IF:**

- $d^*$ maximizes $I_{\text{peak}}^*$ → MPP
DC-Link Capacitor Droop Voltage
Operating direction of $d^*$ in MPPT control:

<table>
<thead>

</tr>
</tbody>
</table>
DC-Link Capacitor Droop Voltage

The ac system line current is fed back to prevent $V_{\text{link}}$ from drooping and $d$ is optimized to bring $I_{\text{peak}}$ to its maximum, thus achieving MPPT.

- DC-link capacitor droop control does not require the computation of the PV array power.
- Its response deteriorates when compared to a direct method.
- Can be easily implemented with analog operational amplifiers and decision-making logic units.
Maximum Power Point Tracking Methods

- P&O (Perturbation in the Operating voltage)
- Increment Conductance
- Fractional Open-Circuit Voltage
- Fractional Short-Circuit Current
- Fuzzy Logic Control
- Neural Network
- RCC (Ripple Correlation Control)
- Current Sweep
- Load Current or Load Voltage Maximization
- DC-Link Capacitor Droop Voltage
- \( \frac{dP}{dV} \) or \( \frac{dP}{dI} \) Feedback Control
dP/dV or dP/dI Feedback Control

1. Reading voltage and current of the array
2. Compute the slope (dP/dV or dP/dI) of the PV power curve (DSP or microcontroller)
3. Feed the slope back to the power converter with some control to drive it to zero.

Computing the slope:

• dP/dV is computed and its sign is stored for the past few cycles.
Based on these signs, the duty ratio of the power converter is either incremented or decremented to reach the MPP.
dP/dV or dP/dI Feedback Control

\[
\begin{align*}
\frac{dP}{dV} &= 0, & \text{at MPP} \\
\frac{dP}{dV} &> 0, & \text{left of MPP} \\
\frac{dP}{dV} &< 0, & \text{right of MPP}
\end{align*}
\]
• Sampling and data conversion are used with subsequent digital division of power and voltage to approximate $dP/dV$. $dP/dI$ is then integrated together with an adaptive gain to improve the transient response.

• The PV array voltage is periodically incremented or decremented and $\Delta P/\Delta V$ is compared to a marginal error until the MPP is reached.
Other MPPT Techniques

✓ **State-based MPPT**

System is represented by a state space model.

A nonlinear time-varying dynamic feedback controller is used to track the MPP.

- Robust
- Insensitive to changes in system parameters
- MPPT is achieved even with:
  1) Changing atmospheric conditions
  2) In the presence of multiple local maxima caused by partially shaded PV array or damaged cells
✓ Single-Stage Inverter

Performs:
1) MPPT
2) Output current regulation for utility grid distribution
Based on the voltage of the PV array, one-cycle control (OCC) is used to adjust the output current of the single-stage inverter such that MPPT is attained.

The control circuit consists of discrete digital components or DSP

• The slight discrepancy is due to the inability of the controller to account for temperature variation.
Other MPPT Techniques

✓ **Best Fixed Voltage (BVF):**

Statistical data is collected about irradiance and temperature levels over a period of one year.

BFV representative of the MPP is found.

The control sets:
operating point of array /BFV or output voltage/nominal load voltage.

• Operation is therefore never exactly at the MPP
• Different data has to be collected for different geographical regions.
Other MPPT Techniques

✓ Linear Reoriented Coordinated Method (LRCM):

The PV array characteristic equation is manipulated to find an approximate symbolic solution for the MPP.

$V_{oc}$, $I_{sc}$, and other constants representing PV array characteristic curve are needed.

• The maximum error in using LRCM to approximate the MPP was found to be 0.3%, but this was based only on simulation results.
Choosing a MPPT Technique

A. Implementation:

Ease of implementation: Depends on user’s knowledge

Analog:
- fractional $I_{sc}$
- fractional $V_{oc}$
- RCC

Load current or voltage maximization

Digital:
- P & O
- IncCond
- Fuzzy Logic Control
- Neural Network
- $dP/dV$ or $dP/dI$ Feedback Control

- Some MPPT techniques only apply to specific topologies:
  - DC-link capacitor droop control
  - OCC works with single-stage inverter
B. Sensors:

The number of sensors required to implement MPPT affects the decision process.

Measuring voltage: Easier More reliable

Current sensors: Expensive Bulky

Problem: systems that consist of several PV arrays with separate MPP trackers.

Sensors to measure irradiance level: hard to find
C. Multiple Local Maxima:

Partial shading of PV array → Multiple local maxima

Considerable power loss can be incurred if a local maximum is tracked instead of the real MPP.

Current sweep

State-base method

Track MPP correctly in presence of local maxima

Other methods:

need additional initial stage to bypass the unwanted local maxima and bring operation to close the real MPP
Choosing a MPPT Technique

D. Costs:

Cost comparison:

- Analog or Digital  \(\rightarrow\) Analog is generally cheaper
- Whether the technique requires software or programming
- Number of sensors  \(\rightarrow\) No current sensor  \(\rightarrow\) Cost
E. Application:

Different MPPT techniques will suit different applications.

- Space satellites/Orbital stations

Costs and complexity: Not important

Performance and reliability: **important**

**MPPT**

1) continuously track the true MPP in minimum time

2) should not require periodic tuning.

Appropriate methods: P&O, IncCond, RCC
Solar vehicles

Mostly require fast convergence to the MPP.

- Load in solar vehicles consists mainly of batteries

Options: Fuzzy logic control Neural networks RCC

Load current or voltage maximization
Residential Areas:

The goal is to minimize the payback time.

Essential to constantly and quickly track the MPP.

Partial shading → MPPT should be capable of bypassing multiple local maxima.

Options: Two-stage IncCond RCC
Street lighting:

PV systems used for street lighting only consist in charging up batteries during the day.

They do not necessarily need tight constraints;

Important factors: Easy Cheap

Options: Fractional $V_{oc}$ Fractional $I_{sc}$
